

# EL9343

# Data Structure and Algorithm

Lecture 3: Divide-and-Conquer algorithms, Introduction to Sorting

Instructor: Yong Liu

Some slides from David Luebke & George Bebis

# Last Lecture: Solving Recurrence

---

- ▶ Recursion tree
  - ▶ Convert recurrence into a tree
  - ▶ Each node represents the cost incurred at various levels of recursion
  - ▶ Sum up the costs of all levels
- ▶ Substitution method
  - ▶ Guess a solution
  - ▶ Use induction to prove that the solution works
- ▶ Master method

# Master's Method

---

- "Cookbook" for solving recurrences of the form:

$$T(n) = aT\left(\frac{n}{b}\right) + f(n)$$

where,  $a \geq 1$ ,  $b > 1$ , and  $f(n) > 0$

- **Case 1:** if  $f(n) = O(n^{\log_b a - \epsilon})$  for some  $\epsilon > 0$ , then  $T(n) = \Theta(n^{\log_b a})$ ;
- **Case 2:** if  $f(n) = \Theta(n^{\log_b a})$ , then  $T(n) = \Theta(n^{\log_b a} \log n)$ ;
- **Case 3:** if  $f(n) = \Omega(n^{\log_b a + \epsilon})$  for some  $\epsilon > 0$ , and if  $af(n/b) \leq cf(n)$  for some  $c < 1$  and all sufficiently large  $n$ , then  $T(n) = \Theta(f(n))$ .

# Today

---

- ▶ Divide-and-conquer algorithms
  - ▶ maximum subarray problem
- ▶ Introduction to sorting
  - ▶ Insertion sort
  - ▶ Bubble sort
  - ▶ Mergesort

# Divide-and-Conquer

---

- ▶ **Divide** the problem into a number of sub-problems
  - ▶ Similar sub-problems of smaller size
- ▶ **Conquer** the sub-problems
  - ▶ Solve the sub-problems recursively
  - ▶ Sub-problem size small enough  $\Rightarrow$  solve the problems in straightforward manner
- ▶ **Combine** the solutions of the sub-problems
  - ▶ Obtain the solution for the original problem
- ▶ Examples: Fibonacci number, binary search

# More Divide-and-Conquer Algorithms

---

- ▶ **Maximum Subarray:** For a given array  $A[1..n]$ , find the contiguous subarray  $A[l..r]$ , such that the summation of  $A[l]+A[l+1]+\dots+A[r]$  is the maximum among all contiguous subarrays

▶ example: A

1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
13	-3	-25	20	-3	-16	-23	18	20	-7	12	-5	-22	15	-4	7

- ▶ Brute-force solution: check all pairs  $\{l,r\}$ ,  $O(n^2)$
- ▶ Divide-and-Conquer:
  - Divide  $A[1..n]$  in the middle:  $A[1,\text{mid}]$ ,  $A[\text{mid}+1,n]$
  - Any subarray  $A[i..j]$  is
    - (1) Entirely in  $A[1,\text{mid}]$
    - (2) Entirely in  $A[\text{mid}+1,n]$
    - (3) In both
  - (1) and (2) can be found recursively, (3) need to find maximum subarray crossing midpoint:  $A[i..\text{mid}]$ ,  $A[\text{mid}+1..j]$ ,  $1 \leq i,j \leq n$
  - Take subarray with largest sum of (1), (2), (3)

# maximum subarray

---

Find-Max-Cross-Subarray(A,low,mid,high)

left-sum =  $-\infty$

sum = 0

**for** i = mid **downto** low

sum = sum + A[i]

**if** sum > left-sum **then**

left-sum = sum

max-left = i

right-sum =  $-\infty$

sum = 0

**for** j = mid+1 **to** high

sum = sum + A[j]

**if** sum > right-sum **then**

right-sum = sum

max-right = j

**return** (max-left, max-right, left-sum + right-sum)

Total time:  $T(n)=2T(n/2)+\Theta(n)$ ,  $T(n)=\Theta(n\log n)$

# The Sorting Problem

---

- ▶ **Input:**

- ▶ A sequence of  $n$  numbers  $a_1, a_2, \dots, a_n$

- ▶ **Output:**

- ▶ A permutation (reordering)  $a_1', a_2', \dots, a_n'$  of the input sequence such that  $a_1' \leq a_2' \leq \dots \leq a_n'$

# Structure of Data

---

- ▶ The numbers to be sorted are part of collection of data called a **record**
- ▶ Each record contains a **key**, which is the value to be sorted

Example of a record

<b>Key</b>	<b>Other data</b>
------------	-------------------

- ▶ Noted that when the key must be arranged, the data associated with the key must also be rearranged (**time consuming!**)
- ▶ Pointer can be used instead (**space consuming!**)

# Why Study Sorting Algorithms?

---

- ▶ Most fundamental problem in algorithm
- ▶ Widely encountered in practice
- ▶ Rich set of classical sorting algorithms using different techniques
- ▶ A variety of situations that we can encounter
  - ▶ Do we have randomly ordered keys?
  - ▶ Are all keys distinct?
  - ▶ How large is the set of keys to be ordered?
  - ▶ Need guaranteed performance?
- ▶ Certain algorithms are better suited to certain situations

# Some Definitions about Sorting

---

- ▶ **Internal Sort**

- ▶ The data to be sorted is all stored in the computer's main memory.

- ▶ **External Sort**

- ▶ Some of the data to be sorted might be stored in some external, slower, device.

- ▶ **In Place Sort**

- ▶ The amount of extra space required to sort the data is constant with the input size.

# Stability

- ▶ A **STABLE** sort preserves relative order of records with equal keys
- ▶ A playing cards example
  - ▶ When the cards are sorted by rank with a **stable sort**, the two 5s must remain in the **same order** in the sorted output that they were originally in.
  - ▶ When they are sorted with a **non-stable sort**, the 5s may end up in the **opposite order** in the sorted output.

# Insertion Sort

---

- ▶ **Idea: like sorting a hand of playing cards**
  - ▶ Start with an empty left hand and the cards facing down on the table.
  - ▶ Remove one card at a time from the table, and insert it into the correct position in the left hand
    - ▶ Compare it with each of the cards already in the left hand, from right to left
  - ▶ The cards held in the left hand are sorted
    - ▶ These cards were originally the top cards of the pile on the table

# Insertion Sort

---

To insert 12, we need to make room for it by moving first 36 and then 24.

# Insertion Sort

---

# Insertion Sort

---

# Insertion Sort

---

Input array

5    2    4    6    1    3

At each iteration, the array is divided in two sub-arrays:

Left sub-array

Right sub-array

# Insertion Sort

# Pseudo-code: insertion sort

---

## INSERTION-SORT( $A$ )

```
1  for  $j = 2$  to  $A.length$ 
2       $key = A[j]$ 
3      // Insert  $A[j]$  into the sorted sequence  $A[1 \dots j - 1]$ .
4       $i = j - 1$ 
5      while  $i > 0$  and  $A[i] > key$ 
6           $A[i + 1] = A[i]$ 
7           $i = i - 1$ 
8       $A[i + 1] = key$ 
```

► In-place?

► Stable?

# Proving Loop Invariants

---

## Proving loop invariants works like induction

- ▶ **Initialization (base case):**
  - ▶ It is true prior to the first iteration of the loop
- ▶ **Maintenance (inductive step):**
  - ▶ If it is true before an iteration of the loop, it remains true before the next iteration
- ▶ **Termination:**
  - ▶ When the loop terminates, the invariant gives us a useful property that helps show that the algorithm is correct
  - ▶ Stop the induction when the loop terminates

# Loop Invariant for Insertion Sort

---

- ▶ **Loop Invariant:**

at the start of each iteration of the for loop, the subarray  $A[1..j-1]$  consists of elements originally in  $A[1..j-1]$ , but in sorted order

- ▶ **Initialization:**

- ▶ Just before the first iteration,  $j = 2$ :

the subarray  $A[1 \dots j-1] = A[1]$ , (the element originally in  $A[1]$ ) – is sorted

# Loop Invariant for Insertion Sort

## ► Maintenance:

- **while** inner loop moves  $A[j-1]$ ,  $A[j-2]$ ,  $A[j-3]$ , and so on, by one position to the right until the proper position for key (which has the value that started out in  $A[j]$ ) is found
- At that point, the value of key is placed into this position.

# Loop Invariant for Insertion Sort

## ► Termination:

- The outer **for** loop ends when  $j = n + 1 \Rightarrow j-1 = n$
- Replace  $n$  with  $j-1$  in the loop invariant:
  - The subarray  $A[1 \dots n]$  consists of the elements originally in  $A[1 \dots n]$ , but in sorted order

The entire array is sorted!

# Running time analysis

---

INSERTION-SORT( $A$ )

	<i>cost</i>	<i>times</i>
1 <b>for</b> $j = 2$ <b>to</b> $A.length$	$c_1$	$n$
2 $key = A[j]$	$c_2$	$n - 1$
3        // Insert $A[j]$ into the sorted sequence $A[1..j - 1]$ .	0	$n - 1$
4 $i = j - 1$	$c_4$	$n - 1$
5 <b>while</b> $i > 0$ and $A[i] > key$	$c_5$	$\sum_{j=2}^n t_j$
6 $A[i + 1] = A[i]$	$c_6$	$\sum_{j=2}^n (t_j - 1)$
7 $i = i - 1$	$c_7$	$\sum_{j=2}^n (t_j - 1)$
8 $A[i + 1] = key$	$c_8$	$n - 1$

# Running time analysis

---

## ▶ running time

$$\begin{aligned} T(n) = & c_1 n + c_2(n-1) + c_4(n-1) + c_5 \sum_{j=2} t_j + c_6 \sum_{j=2} (t_j - 1) \\ & + c_7 \sum_{j=2}^n (t_j - 1) + c_8(n-1) . \end{aligned}$$

## ▶ best case:

$$\begin{aligned} T(n) &= c_1 n + c_2(n-1) + c_4(n-1) + c_5(n-1) + c_8(n-1) \\ &= (c_1 + c_2 + c_4 + c_5 + c_8)n - (c_2 + c_4 + c_5 + c_8) . \end{aligned}$$

## ▶ worst case:

$$\begin{aligned} T(n) &= c_1 n + c_2(n-1) + c_4(n-1) + c_5 \left( \frac{n(n+1)}{2} - 1 \right) \\ &\quad + c_6 \left( \frac{n(n-1)}{2} \right) + c_7 \left( \frac{n(n-1)}{2} \right) + c_8(n-1) \\ &= \left( \frac{c_5}{2} + \frac{c_6}{2} + \frac{c_7}{2} \right) n^2 + \left( c_1 + c_2 + c_4 + \frac{c_5}{2} - \frac{c_6}{2} - \frac{c_7}{2} + c_8 \right) n \\ &\quad - (c_2 + c_4 + c_5 + c_8) . \end{aligned}$$

# Insertion Sort - Summary

---

- ▶ **Advantages**

- ▶ Good running time for “almost sorted” arrays  $\Theta(n)$

- ▶ **Disadvantages**

- ▶  $\Theta(n^2)$  running time in **worst** and **average** case
  - ▶  $\approx n^2/2$  **comparisons** and **exchanges**

# Bubble Sort

---

- ▶ Idea
  - ▶ Repeatedly pass through the array
  - ▶ Swaps adjacent elements that are out of order

- ▶ Easier to implement, but slower than Insertion sort

# Bubble Sort: Example

8	4	6	9	2	3	1
---	---	---	---	---	---	---

$i = 1$        $\leftarrow$  -----  $j$

# Sorting

---

## ▶ Insertion sort

- ▶ Design approach: Incremental
- ▶ Sorts in place: Yes
- ▶ Best case:  $\Theta(n)$
- ▶ Worst case:  $\Theta(n^2)$

## ▶ Bubble Sort

- ▶ Design approach: Incremental
- ▶ Sorts in place: Yes
- ▶ Running time:  $\Theta(n^2)$

# Sorting

---

- ▶ Merge Sort
  - ▶ Design approach: divide and conquer
  - ▶ Sorts in place: No
  - ▶ Running time: Let's see!!

# Merge Sort Approach

---

To sort an array  $A[p \dots r]$ :

- ▶ **Divide**

- ▶ Divide the  $n$ -element sequence to be sorted into two subsequences of  $n/2$  elements each

- ▶ **Conquer**

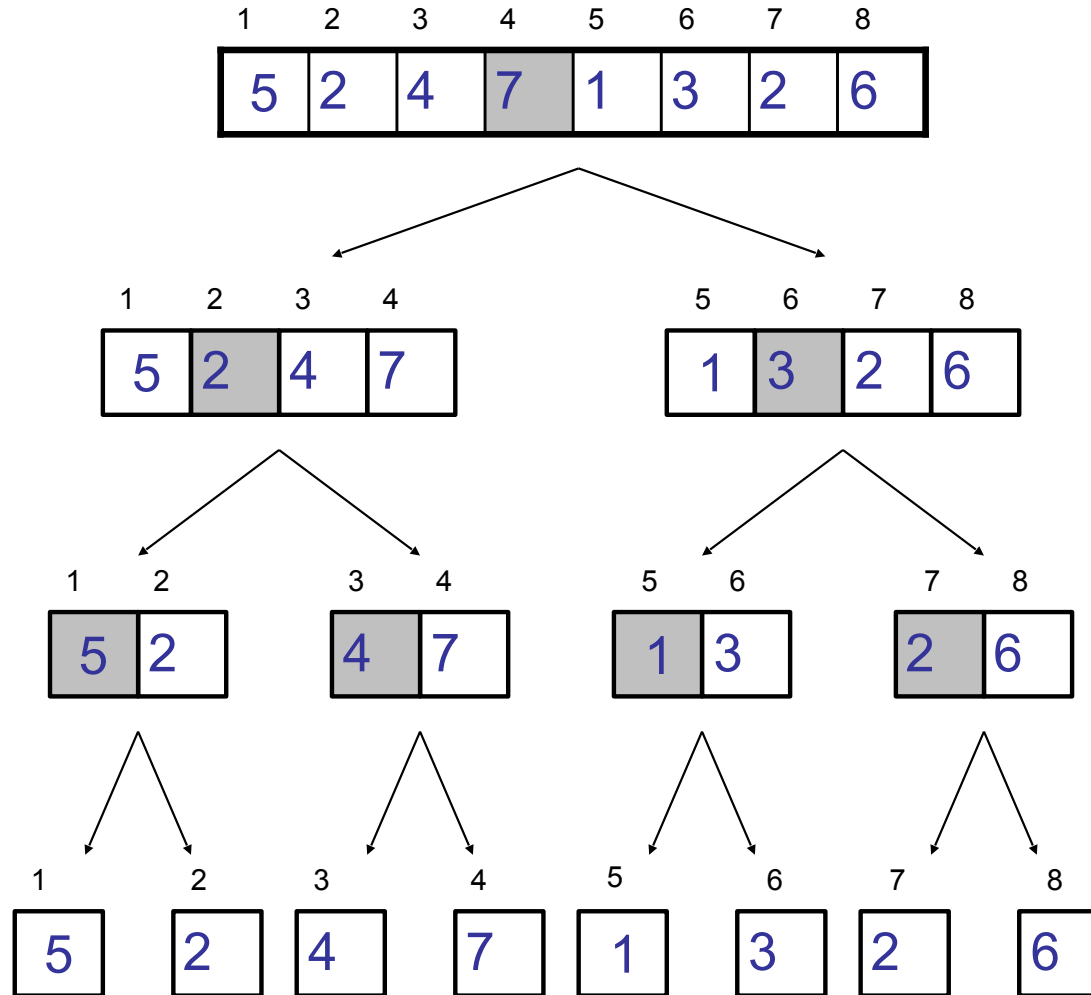

- ▶ Sort the subsequences recursively using merge sort
- ▶ When the size of the sequences is 1 there is nothing more to do

- ▶ **Combine**

- ▶ Merge the two sorted subsequences

# Merge Sort: Example 1

Divide

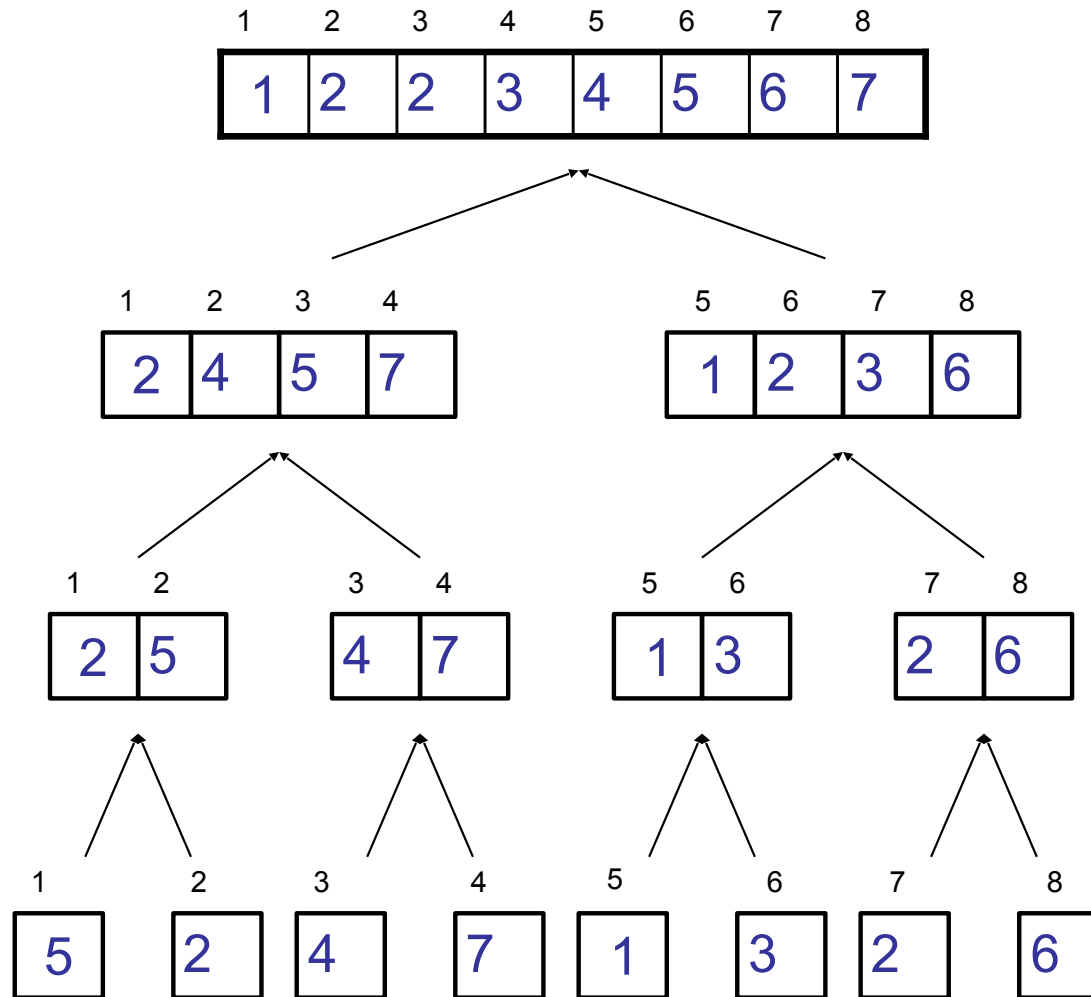

$q = 4$

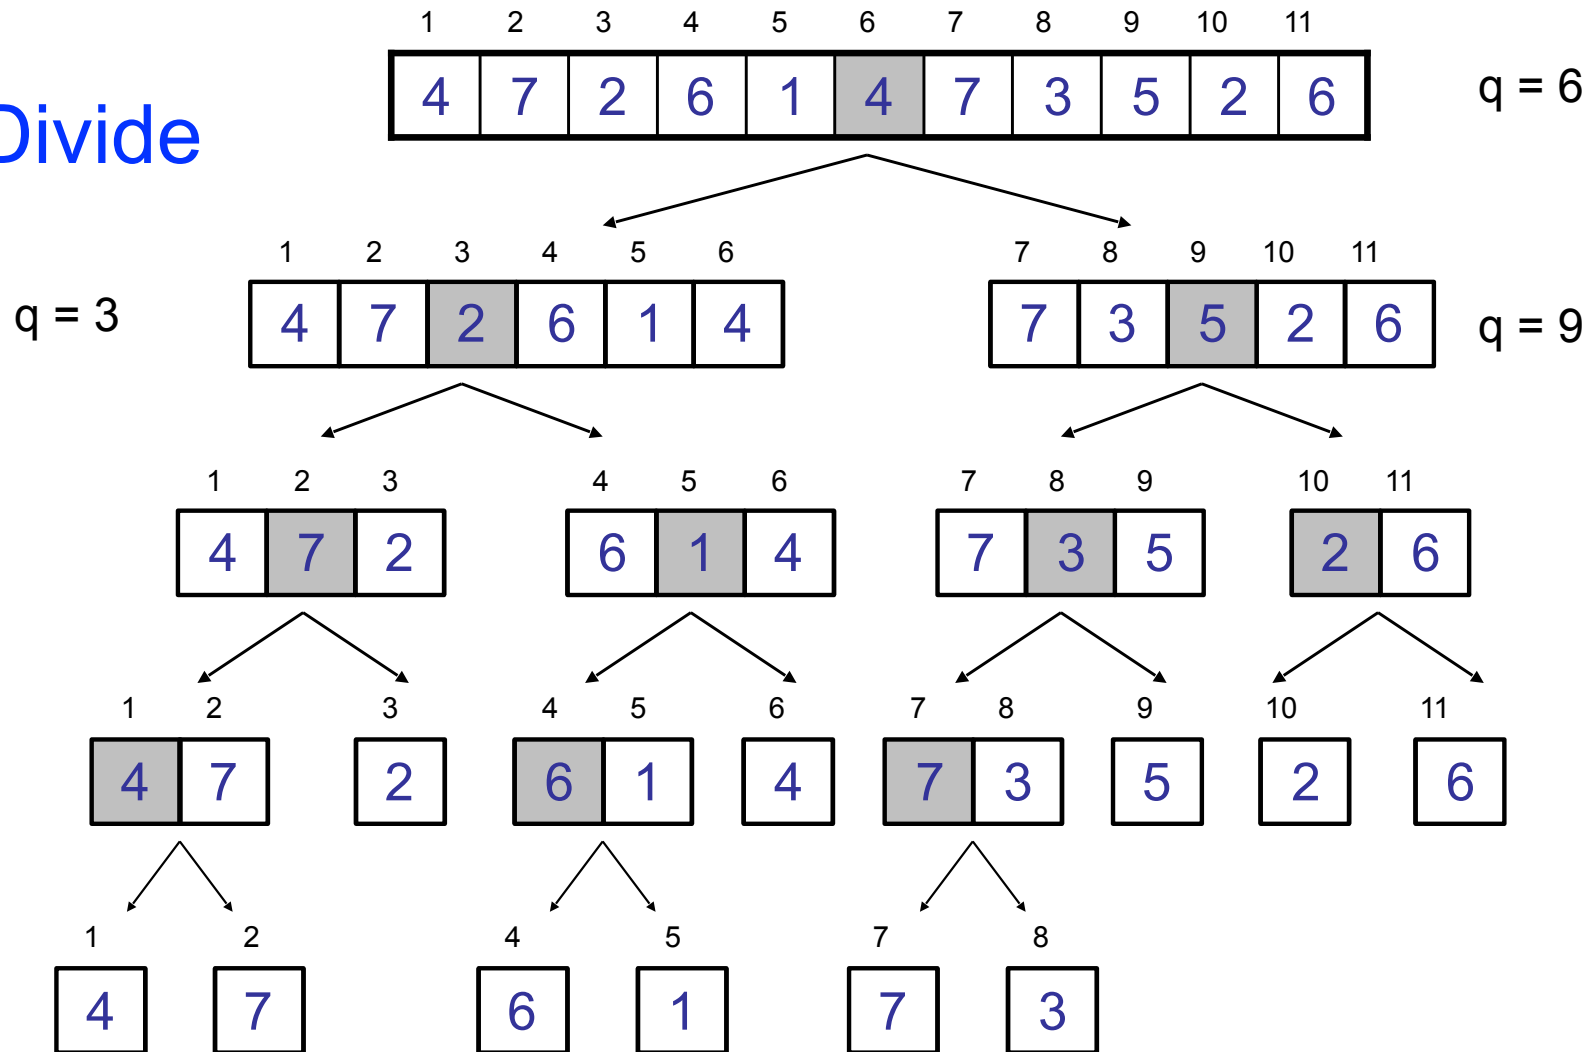

# Merge Sort: Example 1

Conquer  
and  
Merge

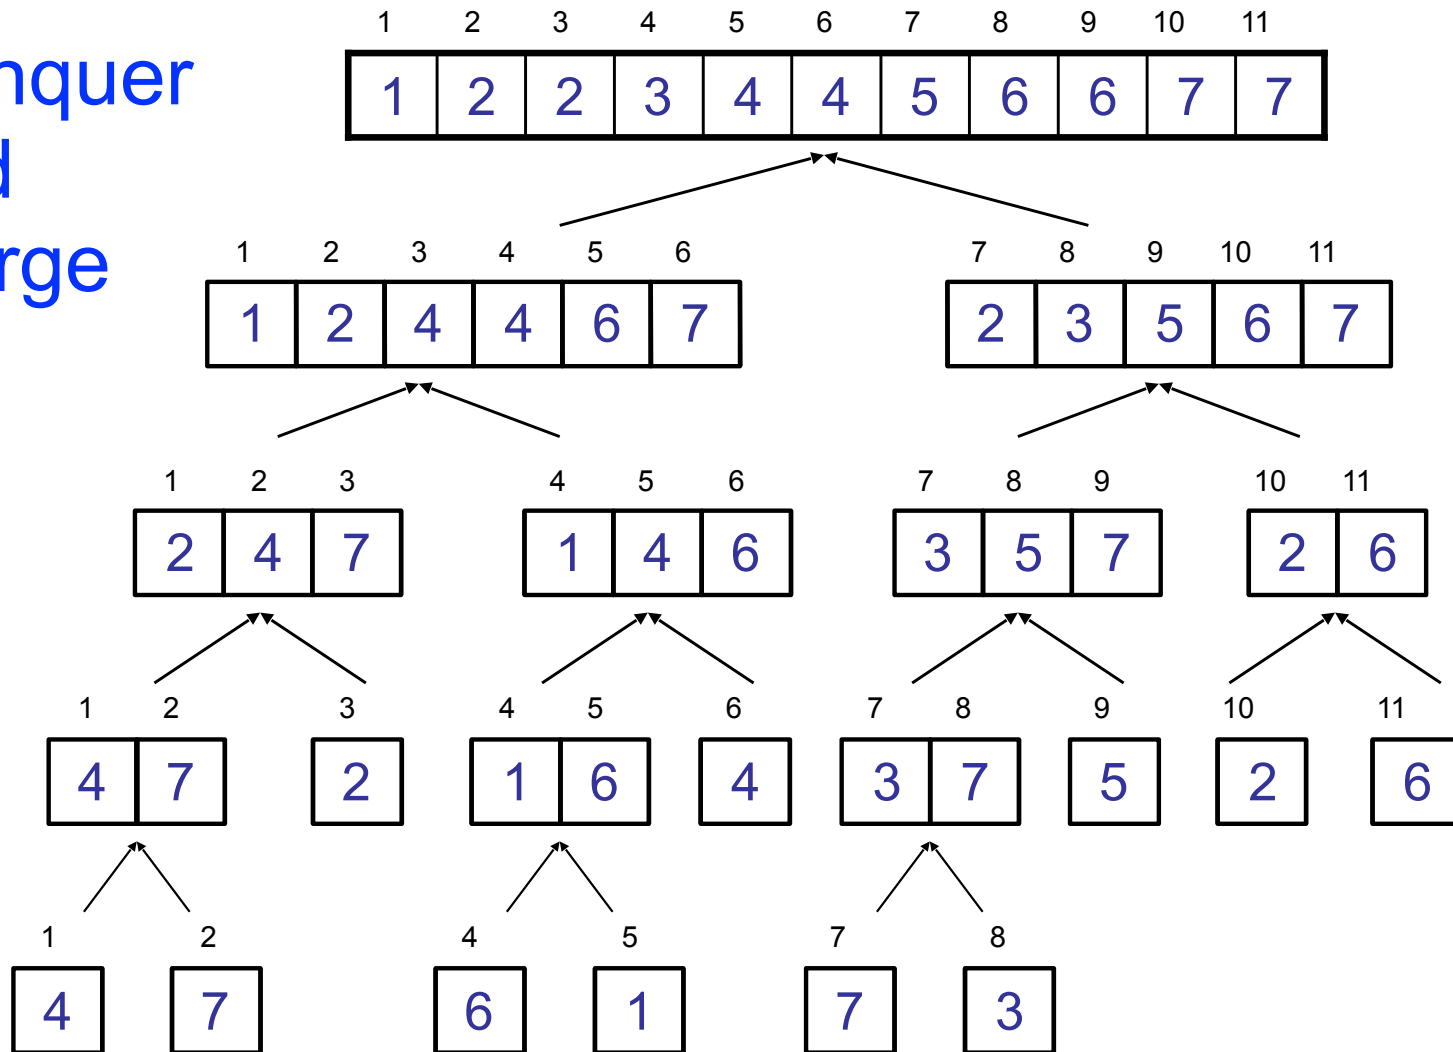

# Merge Sort: Example 2

Divide

# Merge Sort: Example 2

Conquer  
and  
Merge

# Merging

---

- ▶ **Input:** Array A and indices p, q, r such that  $p \leq q < r$ 
  - ▶ Subarrays  $A[p \dots q]$  and  $A[q + 1 \dots r]$  are sorted
- ▶ **Output:** One single sorted subarray  $A[p \dots r]$

# Merging

## ▶ Idea for merging

### ▶ Two piles of sorted cards

- ▶ Choose the smaller of the two top cards
- ▶ Remove it and place it in the output pile

### ▶ Repeat the process until one pile is empty

### ▶ Take the remaining input pile and place it face-down onto the output pile

$A_1 \leftarrow A[p, q]$

$A_2 \leftarrow A[q+1, r]$

choose the smaller  
element from the subarrays

$A[p, r]$

# Example: MERGE(A, 9, 12, 16)

# Example: MERGE(A, 9, 12, 16)

# Example: MERGE(A, 9, 12, 16)

# Example: MERGE(A, 9, 12, 16)

# Example: MERGE(A, 9, 12, 16)

---

Done!

► In Place?

# Merge Sort Running Time

---

- ▶ **Divide:**

- ▶ Compute  $q$  as the average of  $p$  and  $r$ :  $D(n) = \Theta(1)$

- ▶ **Conquer:**

- ▶ Recursively solve 2 subproblems, each of size  $n/2$   
 $\Rightarrow 2T(n/2)$

- ▶ **Combine:**

- ▶ MERGE on an  $n$ -element subarray takes  $\Theta(n)$  time  
 $\Rightarrow C(n) = \Theta(n)$

$$T(n) = \begin{cases} \Theta(1) & \text{if } n = 1 \\ 2T(n/2) + \Theta(n) & \text{if } n > 1 \end{cases}$$

# Solve the Recurrence

---

$$T(n) = \begin{cases} c & \text{if } n = 1 \\ 2T(n/2) + cn & \text{if } n > 1 \end{cases}$$

Use Master's Theorem:

Compare  $n$  with  $f(n) = cn$

Case 2:  $T(n) = \Theta(n \lg n)$

# Merge Sort - Discussion

---

- ▶ Running time insensitive of the input
- ▶ **Advantages**
  - ▶ Guaranteed to run in  $\Theta(n \lg n)$
- ▶ **Disadvantage**
  - ▶ Requires extra space  $\approx n$

# Sorting Challenge 1

---

**Problem:** Sort a **huge** randomly-ordered file of small records

**Application:** Process transaction record for a phone company

**Which sorting method to use?**

- A. Bubble sort
- B. Mergesort guaranteed to run in time  $\sim n \log n$
- C. Insertion sort

# Sorting Huge, Randomly-Ordered Files

---

- ▶ Bubble sort?
  - ▶ NO, quadratic time for randomly-ordered keys
- ▶ Insertion sort?
  - ▶ NO, quadratic time for randomly-ordered keys
- ▶ Mergesort?
  - ▶ YES, it is designed for this problem

# Sorting Challenge 2

---

- ▶ **Problem:** sort a file that is already almost in order
- ▶ **Applications:**
  - ▶ Re-sort a huge database after a few changes
  - ▶ Double check that someone else sorted a file
- ▶ **Which sorting method to use?**
  - ▶ Mergesort, guaranteed to run in time  $\sim n \lg n$
  - ▶ Bubble sort
  - ▶ Insertion sort

# Sorting Files That are Almost in Order

---

- ▶ Bubble sort?

- ▶ **NO**, bad for some definitions of “almost in order”
- ▶ Ex: B C D E F G H I J K L M N O P Q R S T U V W X Y Z A

- ▶ Insertion sort?

- ▶ **YES**, takes linear time for most definitions of “almost in order”

- ▶ Mergesort or custom method?

- ▶ **Probably not**: insertion sort simpler and faster

# What's next...

---

- ▶ More sorting algorithms
  - ▶ Heapsort
  - ▶ Quicksort
  - ▶ ...
