Data Structure and Algorithm

Lecture 5: Randomized Quick Sort, Sorting Lower Bound, Order Statistics & Selection

Instructor: Yong Liu

Last Lecture

- ▶ Heapsort & Priority Queue
 - ▶ MAX-HEAPIFY $O(\lg n)$
 - ▶ BUILD-MAX-HEAP $O(n)$
 - ▶ HEAP-SORT $O(n \lg n)$
 - ▶ MAX-HEAP-INSERT $O(\lg n)$
 - ▶ HEAP-EXTRACT-MAX $O(\lg n)$
 - ▶ HEAP-INCREASE-KEY $O(\lg n)$
 - ▶ HEAP-MAXIMUM $O(1)$

Last Lecture

Quicksort

► Divide

- Partition the array A into 2 subarrays $A[p..q]$ and $A[q+1..r]$, such that each element of $A[p..q]$ is smaller than or equal to each element in $A[q+1..r]$
- Need to find index q to partition the array

Quicksort

► Conquer

- Recursively sort $A[p..q]$ and $A[q+1..r]$ by calls to Quicksort

► Combine (unlike merge sort)

- Trivial: the arrays are sorted in place
- No additional work is required to combine them
- The entire array is now sorted

Quicksort: Recurrence

Alg.: QUICKSORT(A, p, r)

if $p < r$

then $q \leftarrow \text{PARTITION}(A, p, r)$

QUICKSORT (A, p, q)

QUICKSORT (A, q+1, r)

Initially: $p=1, r=n$

Recurrence: $T(n) = T(q) + T(n - q) + n$

Analyzing Quicksort: Worst Case Partitioning

▶ Worst-case partitioning

- ▶ One region has one element and the other has $n - 1$ elements
- ▶ Maximally unbalanced

▶ Recurrence: $q=1$

$$T(n) = T(1) + T(n - 1) + n,$$

- ▶ $T(1) = \Theta(1)$

- ▶ $T(n) = T(n - 1) + n$

$$= n + \left(\sum_{k=1}^n k \right) - 1 = \Theta(n) + \Theta(n^2) = \Theta(n^2)$$

When does the worst case happen?

Analyzing Quicksort: Best Case Partitioning

- ▶ Best-case partitioning
 - ▶ Partitioning produces two regions of size $n/2$
- ▶ Recurrence: $q=n/2$
 - ▶ $T(n) = 2T(n/2) + \Theta(n)$
 - ▶ $T(n) = \Theta(n \lg n)$ (Master theorem)

Randomized Algorithm

- ▶ No input can elicit worst case behavior
 - ▶ Worst case occurs only if we get “unlucky” numbers from the random number generator
- ▶ Worst case becomes less likely
 - ▶ Randomization can NOT eliminate the worst-case but it can make it less likely!

Randomizing Quicksort

- ▶ Randomly permute the elements of the input array before sorting
- ▶ OR ... modify the PARTITION procedure
 - ▶ At each step of the algorithm we exchange element $A[p]$ with an element chosen at random from $A[p..r]$
 - ▶ The pivot element $x = A[p]$ is equally likely to be any one of the $r - p + 1$ elements of the subarray

Randomizing PARTITION

Alg.: RANDOMIZED-PARTITION(A, p, r)

*Random choose
and exchange.* $\left\{ \begin{array}{l} i \leftarrow \text{RANDOM}(p, r) \\ \text{exchange } A[p] \leftrightarrow A[i] \end{array} \right.$

return PARTITION(A, p, r)

Different Partition Method

Another Partitioning: Lomuto's Partition

Given an array A, partition the array into the following subarrays:

- ▶ A pivot element $x = A[q]$
- ▶ Subarray $A[p..q-1]$ such that each element of $A[p..q-1]$ is smaller than or equal to x (the pivot)
- ▶ Subarray $A[q+1..r]$, such that each element of $A[q+1..r]$ is strictly greater than x (the pivot)
- ▶ The pivot element is not included in any of the two subarrays

Randomizing Quicksort using Lomuto's partition

Alg.:RANDOMIZED-QUICKSORT(A, p, r)

if $p < r$

then $q \leftarrow \text{RANDOMIZED-PARTITION}(A, p, r)$

RANDOMIZED-QUICKSORT($A, p, q - 1$)

RANDOMIZED-QUICKSORT($A, q + 1, r$)

q in the final position solved.

The pivot is no longer included in any of the subarrays!!

Analysis of Randomized Quicksort

Alg.:RANDOMIZED-QUICKSORT(A, p, r)

if $p < r$

then $q \leftarrow \text{RANDOMIZED-PARTITION}(A, p, r)$

RANDOMIZED-QUICKSORT($A, p, q - 1$)

RANDOMIZED-QUICKSORT($A, q + 1, r$)

PARTITION is called at most n times

- ▶ (at each call a pivot is selected and never again included in future calls)

Partition

Two pointers

Alg.: PARTITION(A, p, r)

$x \leftarrow A[r]$: *use the last element as x*

$i \leftarrow p - 1$

} $O(1)$ - constant

for $j \leftarrow p$ **to** $r - 1$

do if $A[j] \leq x$

then $i \leftarrow i + 1$

exchange $A[i] \leftrightarrow A[j]$

} # of comparisons: X_k
between the pivot and
the other elements

exchange $A[i + 1] \leftrightarrow A[r]$: x

} $O(1)$ - constant

return $i + 1$

Amount of work at call k : $c + X_k$

ratio is random. How to analysis it? what's the average case?

Average-Case Analysis of Quicksort

- ▶ Let X = total number of comparisons performed in all calls to PARTITION:

$$T = \left(\sum_{k=1}^n C + X_k \right) = O(nc + X)$$

\downarrow current

- ▶ The total work done over the **entire** execution of Quicksort is

$$O(nc + X) = O(n + X)$$

- ▶ Need to estimate $E(X)$: the average number of comparisons in all calls with random partition at each call.

Review of Probabilities

- **Definitions**

- random experiment: an experiment whose result is not certain in advance (e.g., throwing a die)
- outcome: the result of a random experiment
- sample space: the set of all possible outcomes (e.g., $\{1,2,3,4,5,6\}$)
- event: a subset of the sample space (e.g., obtain an odd number in the experiment of throwing a die = $\{1,3,5\}$)

Review of Probabilities

- **Probability of an event**

- The likelihood that an event will occur if the underlying random experiment is performed

$$P(event) = \frac{\text{number of favorable outcomes}}{\text{total number of possible outcomes}}$$

Example: $P(\text{obtain an odd number}) = 3/6 = 1/2$

Random Variables

- ▶ **Def.:** **(Discrete) random variable X :** a function from a sample space S to the real numbers.
- ▶ It associates a real number with each possible outcome of an experiment.

Random Variables

E.g.: Toss a coin three times

define X = “numbers of heads”

Computing Probabilities Using Random Variables

- Example: consider the experiment of throwing a pair of dice

Define the r.v. X ="sum of dice"

$X = x$ corresponds to the event $A_x = \{s \in S / X(s) = x\}$

(e.g., $X = 5$ corresponds to $A_5 = \{(1,4), (4,1), (2,3), (3,2)\}$)

$$P(X = x) = P(A_x) = \sum_{s: X(s)=x} P(s)$$

$$(P(X = 5) = P((1, 4)) + P((4, 1)) + P((2, 3)) + P((3, 2)) = 4/36 = 1/9)$$

Expectation

- ▶ Expected value (expectation, mean) of a discrete random variable X is:

$$E[X] = \sum_x x \Pr\{X = x\}$$

- ▶ “Average” over all possible values of random variable X

Examples

Example: X = face of one fair dice

$$E[X] = 1 \cdot 1/6 + 2 \cdot 1/6 + 3 \cdot 1/6 + 4 \cdot 1/6 + 5 \cdot 1/6 + 6 \cdot 1/6 \\ = 3.5$$

Example: $\therefore X$ = "sum of dice"

Events												
Sum	1	2	3	4	5	6	7	8	9	10	11	12
Probability	0/36	1/36	2/36	3/36	4/36	5/35	6/36	5/36	4/360	3/36	2/36	1/36

$$E(X) = 1P(X = 1) + 2P(X = 2) + \dots + 12P(X = 12) = (0 + 2 + \dots + 12)/36 = 7$$

Indicator Random Variables

- ▶ Given a sample space S and an event A , we define the ***indicator random variable*** $I\{A\}$ associated with A :
 - ▶
$$I\{A\} = \begin{cases} 1 & \text{if } A \text{ occurs} \\ 0 & \text{if } A \text{ does not occur} \end{cases}$$
- ▶ The expected value of an indicator random variable $X_A = I\{A\}$:
 - ▶ $E[X_A] = \Pr\{A\}$
- ▶ **Proof:** $E[X_A] = E[I\{A\}] = 1 * \Pr\{A\} + 0 * \Pr\{\bar{A}\} = \Pr\{A\}$

Average-Case Analysis of Quicksort

- ▶ Let X = **total number of comparisons performed in all calls to PARTITION:**
- ▶ The total work done over the **entire** execution of Quicksort is $O(n+X)$
- ▶ Need to estimate $E(X)$: the average number of comparisons in all calls with random partition at each call.

Comparisons in PARTITION : Observation 1

- ▶ Each pair of elements is compared **at most once** during the entire execution of the algorithm
 - ▶ Elements are compared only to the pivot point
 - ▶ Pivot point is excluded from future calls to PARTITION

Notation

z_2	z_9	z_8	z_3	z_5	z_4	z_1	z_6	z_{10}	z_7
2	9	8	3	5	4	1	6	10	7

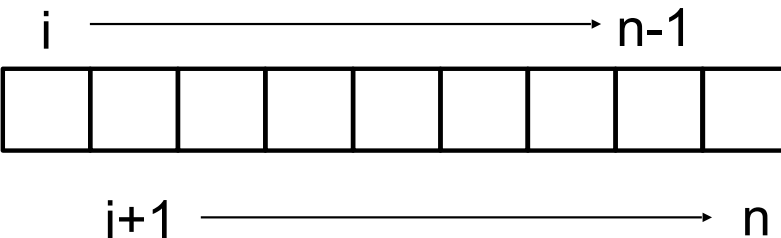

Notation:

- ▶ Rename the elements of A as z_1, z_2, \dots, z_n , with z_i being the i -th smallest element

$$\text{len}(Z_{ij}) = j - i + 1$$
- ▶ Define the set $Z_{ij} = \{z_i, z_{i+1}, \dots, z_j\}$ the set of elements between z_i and z_j , inclusive

Total Number of Comparisons in PARTITION

- ▶ Define $X_{ij} = 1$ if $\{z_i \text{ is compared to } z_j\}$ or 0
- ▶ Total number of comparisons X performed by the algorithm:

$$X = \sum_{i=1}^{n-1} \sum_{j=i+1}^n X_{ij}$$

The diagram illustrates an array of size n . The first element is indexed i and the last element is indexed $n-1$. Below the array, the range from $i+1$ to n is indicated, representing the elements compared to the element at index i .

Expected Number of Total Comparisons in PARTITION

- Compute the **expected value of X** :

$i \wedge j = X_{ij}$: smallest; X_{ij} = largest.

$$E[X] = E\left[\sum_{i=1}^{n-1} \sum_{j=i+1}^n X_{ij}\right] = \sum_{i=1}^{n-1} \sum_{j=i+1}^n E[X_{ij}]$$

by linearity
of expectation

indicator
random variable

$$= \sum_{i=1}^{n-1} \sum_{j=i+1}^n \Pr\{z_i \text{ is compared to } z_j\}$$

the expectation of X_{ij} is equal
to the probability of the event
“ z_i is compared to z_j ”

Comparisons in PARTITION : Observation 2

- ▶ Only the pivot is compared with elements in both partitions!

Elements between different partitions
are never compared!

Comparisons in PARTITION

z_2	z_9	z_8	z_3	z_5	z_4	z_1	z_6	z_{10}	z_7
2	9	8	3	5	4	1	6	10	7

$$Z_{1,6} = \{1, 2, 3, 4, 5, 6\} \quad \{7\} \quad Z_{8,9} = \{8, 9, 10\}$$

$$A = \Pr\{z_i \text{ is compared to } z_j\}?$$

- ▶ **Case 1: pivot x chosen such as: $z_i < x < z_j$**
 - ▶ z_i and z_j will never be compared $A = \Pr\{\dots\} = 0$
- ▶ **Case 2: z_i or z_j is the pivot** $A = \Pr\{\dots\} =$
 - ▶ z_i and z_j will be compared
 - ▶ only if one of them is chosen as pivot before any other element in range z_i to z_j *before case 1: can be combined.*

Let's See Why

z_2 will never be compared with z_6 since z_5 (which belongs to $[z_2, z_6]$) was chosen as a pivot first !

Probability of comparing z_i with z_j

$\Pr\{z_i \text{ is compared to } z_j\}$

$$\begin{aligned} &= \Pr\{z_i \text{ is the first pivot chosen from } Z_{ij}\} + \Pr\{z_j \text{ is the first pivot chosen from } Z_{ij}\} \\ &= 1/(j - i + 1) + 1/(j - i + 1) = 2/(j - i + 1) \end{aligned}$$

Handwritten note: 5, 6, 7, should not be chosen before until 4 or 8 is chosen.

- ▶ There are $j - i + 1$ elements between z_i and z_j
 - ▶ Pivot is chosen randomly and independently
 - ▶ The probability that any particular element is the first one chosen is $1/(j - i + 1)$

Number of Comparisons in PARTITION

Expected number of comparisons in PARTITION:

$$E[X] = \sum_{i=1}^{n-1} \sum_{j=i+1}^n \Pr\{z_i \text{ is compared to } z_j\}$$
$$E[X] = \sum_{i=1}^{n-1} \sum_{j=i+1}^n \frac{2}{j-i+1} = \sum_{i=1}^{n-1} \sum_{k=1}^{n-i} \frac{2}{k+1} < \sum_{i=1}^{n-1} \sum_{k=1}^n \frac{2}{k} = \sum_{i=1}^{n-1} O(\lg n)$$

(set $k=j-i$) (harmonic series)

$$= O(n \lg n)$$

⇒ Expected running time of Quicksort using RANDOMIZED-PARTITION is **$O(n \lg n)$**

Sorting So Far ...

- ▶ Insertion sort:
 - ▶ Easy to code
 - ▶ Fast on small inputs (less than ~50 elements)
 - ▶ Fast on nearly-sorted inputs
 - ▶ $O(n^2)$ worst case
 - ▶ $O(n^2)$ average (equally-likely inputs) case
 - ▶ $O(n^2)$ reverse-sorted case

Sorting So Far ...

- ▶ Merge sort:
 - ▶ Divide-and-conquer approach
 - ▶ Split array in half
 - ▶ Recursively sort subarrays
 - ▶ Linear-time merge step
 - ▶ $O(n \lg n)$ worst case
 - ▶ Doesn't sort in place

Sorting So Far ...

- ▶ Heap sort:
 - ▶ Uses the very useful heap data structure
 - ▶ Complete binary tree
 - ▶ Heap property: parent key $>$ children's keys
 - ▶ $O(n \lg n)$ worst case
 - ▶ Sorts in place
 - ▶ Not stable

Sorting So Far ...

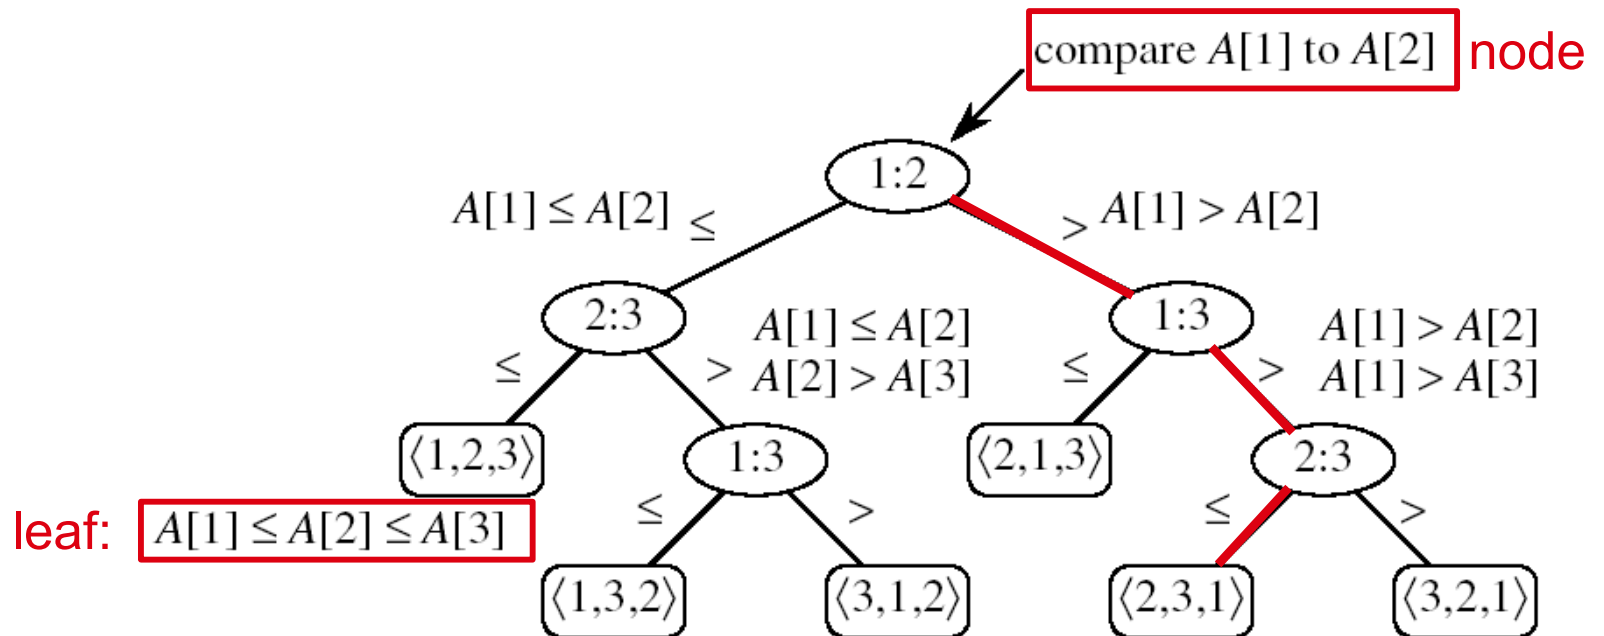

- ▶ Quick sort:
 - ▶ Divide-and-conquer:
 - ▶ Partition array into two subarrays, recursively sort
 - ▶ No merge step needed!
 - ▶ $O(n \lg n)$ average case
 - ▶ Fast in practice
 - ▶ $O(n^2)$ worst case
 - ▶ Naïve implementation: worst case on sorted input
 - ▶ Address this with randomized quicksort

How Fast Can We Sort?

- ▶ We will provide a lower bound, then beat it
 - ▶ *How do you suppose we'll beat it?*
- ▶ First, an observation: all of the sorting algorithms so far are comparison sorts *only compare, don't care the number.*
 - ▶ The only operation used to gain ordering information about a sequence is the pairwise comparison of two elements
 - ▶ Theorem: all comparison sorts are $\Omega(n \lg n)$

Decision Trees

- ▶ *Decision trees* provide an abstraction of comparison sorts
 - ▶ A decision tree represents the comparisons made by a comparison sort. Everything else ignored
- ▶ *What do the leaves represent?*
- ▶ *How many leaves must there be?*

Decision Trees

- ▶ Decision trees can model comparison sorts. For a given algorithm:
 - ▶ One tree for each n
 - ▶ Tree paths are all possible execution traces
 - ▶ Worst-case number of comparisons depends on the length of the longest path from the root to a leaf (i.e., the height of the decision tree)
- ▶ *What is the asymptotic height of any decision tree for sorting n elements?*
 - ▶ Answer: $\Omega(n \lg n)$ (now let's prove it...)

The minimum # of leaves of a decision tree

- All permutations on n elements must appear as one of the leaves in the decision tree: $n!$ permutations
- At least $n!$ leaves

Any binary tree of height h has at most 2^h leaves

Lower Bound For Comparison Sorting

- ▶ **Theorem:** Any decision tree that sorts n elements has height $\Omega(n \lg n)$

- ▶ So we have: $n! \leq 2^h$

- ▶ Taking logarithms: $\lg(n!) \leq h$

- ▶ Stirling's approximation tells us: $n! > \left(\frac{n}{e}\right)^n$

- ▶ Thus: $\underset{\Delta}{h} \geq \lg\left(\frac{n}{e}\right)^n$: More details on the book
if interested

$$= n \lg n - n \lg e$$

$$= \Omega(n \lg n)$$

Sorting In Linear Time

Counting sort - no comparisons between elements!

► Assumptions

- Sort n integers which are in the range $[0 \dots r]$
- r is in the order of n , that is, $r = O(n)$

Not General model

► Idea

- For each element x , find the number of elements $\leq x$
- Place x into its correct position in the output array

input array A:

3	6	4	2	5	8	10
---	---	---	---	---	---	----

$x=5$, number of elements $\leq 5 = 4$ {3,4,2,5}

input array B:

--	--	--	--	--	--	--

put 5 here !!!

Step1: find the no. of times integer $A[i]$ appears in A

input array A:

3	6	4	1	3	4	1	4
---	---	---	---	---	---	---	---

allocate C

1	2	3	4	5	6
0	0	0	0	0	0

Allocate $C[1..r]$ (histogram)

$i=1, A[1]=3$

1	2	3	4	5	6
0	0	1	0	0	0

$C[A[1]]=C[3]=1$ For $1 \leq i \leq n, ++C[A[i]]$;

$i=2, A[2]=6$

1	2	3	4	5	6
0	0	1	0	0	1

$C[A[2]]=C[6]=1$

$i=3, A[3]=4$

1	2	3	4	5	6
0	0	1	1	0	1

$C[A[3]]=C[4]=1$

⋮

$i=8, A[8]=4$

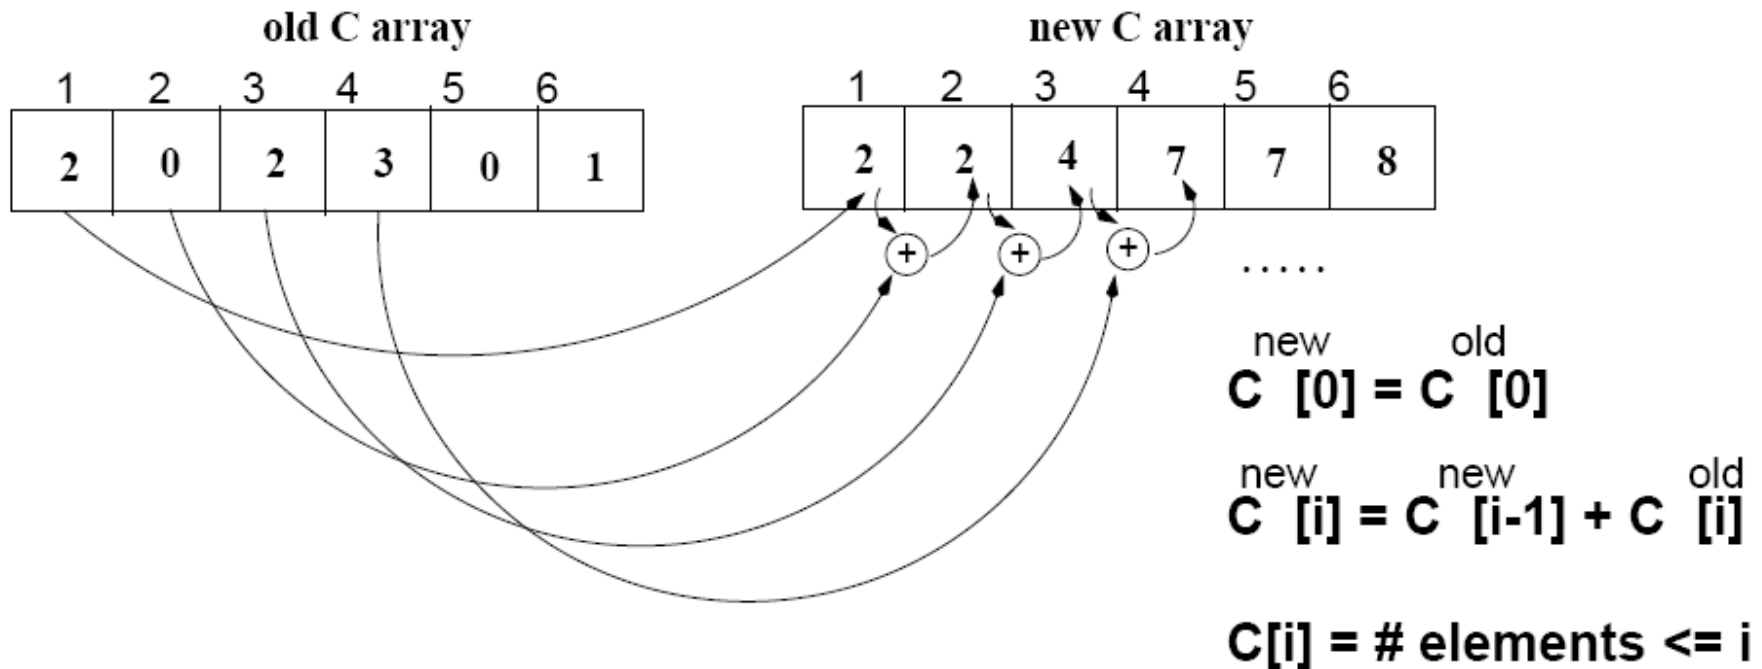

1	2	3	4	5	6
2	0	2	3	0	1

$C[A[8]]=C[4]=3$

$C[i]$ = number of times element i appears in A (i.e., frequencies)

Step 2: find the no. of elements $\leq A[i]$

(i.e., cumulative sums)

Analysis of Counting Sort

Alg.: COUNTING-SORT(A, B, n, k)

1. **for** $i \leftarrow 0$ **to** r
2. **do** $C[i] \leftarrow 0$
3. **for** $j \leftarrow 1$ **to** n
4. **do** $C[A[j]] \leftarrow C[A[j]] + 1$
 $C[i]$ contains the number of elements equal to i
5. **for** $i \leftarrow 1$ **to** r
6. **do** $C[i] \leftarrow C[i] + C[i-1]$
 $C[i]$ contains the number of elements $\leq i$
7. **for** $j \leftarrow n$ **downto** 1
8. **do** $B[C[A[j]]] \leftarrow A[j]$
9. $C[A[j]] \leftarrow C[A[j]] - 1$

~~Example~~

start from back

Example

A

1	2	3	4	5	6	7	8
2	5	3	0	2	3	0	3

B

1	2	3	4	5	6	7	8
0	0		2		3	3	
0	1	2	3	4	5		

C

0	2	3	5	7	8
---	---	---	---	---	---

B

1	2	3	4	5	6	7	8
0	0		2	3	3	3	
0	1	2	3	4	5		

C

0	2	3	4	7	8
---	---	---	---	---	---

B

1	2	3	4	5	6	7	8
0	0		2	3	3	3	5
0	1	2	3	4	5		

C

0	2	3	4	7	7
---	---	---	---	---	---

B

1	2	3	4	5	6	7	8
0	0	2	2	3	3	3	5

Analysis of Counting Sort

Alg.: COUNTING-SORT(A, B, n, k)

1. **for** $i \leftarrow 0$ **to** r
2. **do** $C[i] \leftarrow 0$
3. **for** $j \leftarrow 1$ **to** n
4. **do** $C[A[j]] \leftarrow C[A[j]] + 1$
- $C[i]$ contains the number of elements equal to i
5. **for** $i \leftarrow 1$ **to** r
6. **do** $C[i] \leftarrow C[i] + C[i-1]$
- $C[i]$ contains the number of elements $\leq i$
7. **for** $j \leftarrow n$ **downto** 1
8. **do** $B[C[A[j]]] \leftarrow A[j]$
9. $C[A[j]] \leftarrow C[A[j]] - 1$

$\Theta(r)$

$\Theta(n)$

$\Theta(r)$

$\Theta(n)$

Overall time: $\Theta(n + r)$

Counting Sort

- ▶ Overall time: $\Theta(n + r)$
- ▶ In practice we use COUNTING sort when $r = O(n)$
 \Rightarrow running time is $\Theta(n)$
- ▶ Counting sort is stable
- ▶ Counting sort is not in place sort

Radix Sort

- ▶ Represents keys as d-digit numbers in some base-k
 - ▶ e.g., $\text{key} = x_1x_2\dots x_d$ where $0 \leq x_i \leq k-1$
- ▶ Example: $\text{key}=15$
 - ▶ $\text{key}_{10} = 15$, $d=2$, $k=10$ where $0 \leq x_i \leq 9$
 - ▶ $\text{key}_2 = 1111$, $d=4$, $k=2$ where $0 \leq x_i \leq 1$

Radix Sort

Assumptions

- ▶ $d = \Theta(1)$ and $k = O(n)$

Sorting looks at one column at a time

- ▶ For a d digit number, sort the least significant digit first, using a stable sort algorithm
- ▶ Continue sorting on the next least significant digit, (stable sort) until all digits have been sorted
- ▶ Requires only d passes through the list

- ▶ Running time: $O(d(n+k))$

column: 1 2 3
↓ ↓ ↓
326
453
608
835
751
435
704
690

Sort column order = 3, 2, 1

least significant digit

Order Statistics

- ▶ The *i -th order statistic* in a set of n elements is the *i -th* smallest element
- ▶ The *minimum* is thus the 1st order statistic
- ▶ The *maximum* is the n -th order statistic
- ▶ The *median* is the $n/2$ -th order statistic
 - ▶ If n is even, there are 2 medians
- ▶ *How can we calculate order statistics?*
- ▶ *What is the running time?*

Order Statistics

- ▶ *How many comparisons are needed to find the minimum element in a set? The maximum?*
- ▶ *Can we find the minimum and maximum with less than twice the cost? Assignment 3.*
- ▶ Yes
 - ▶ Walk through elements by pairs
 - ▶ Compare each element in pair to the other
 - ▶ Compare the largest to maximum, smallest to minimum
 - ▶ Total cost: 3 comparisons per 2 elements = $O(3n/2)$

Finding Order Statistics: The Selection Problem

- ▶ A more interesting problem is *selection*: finding the *i*-th smallest element of a set — *Randomize Sort*
- ▶ We will show: *Partition*
 - ▶ A practical randomized algorithm with $O(n)$ expected running time
 - ▶ A cool algorithm of theoretical interest only with $O(n)$ worst-case running time

Randomized Selection

- ▶ Key idea: use `partition()` from quicksort
 - ▶ But, only need to examine one subarray
 - ▶ This savings shows up in running time: $O(n)$
 - ▶ $q = \text{RandomizedPartition}(A, p, r)$

Randomized Selection

RandomizedSelect(A, p, r, i)

if (p == r) then return A[p];

q = RandomizedPartition(A, p, r)

k = q - p + 1;

if (i == k) then return A[q]; *// the pivot value is the answer*

if (i < k) then

return RandomizedSelect(A, p, q-1, i);

else

return RandomizedSelect(A, q+1, r, i-k);

Analyzing Randomized Selection

- ▶ Worst case: partition always 0:n-1
 - ▶ $T(n) = T(n-1) + O(n) = ???$
 $= O(n^2)$ (arithmetic series)
 - ▶ No better than sorting!
- ▶ “Best” case: suppose a 9:1 partition
 - ▶ $T(n) = T(9n/10) + O(n) = ???$
 $= O(n)$ (Master Theorem, case 3)
 - ▶ Better than sorting!

Analyzing Randomized Selection

- ▶ Average case

- ▶ For upper bound, assume i-th element always falls in larger side of partition:

$$T(n) \leq \frac{1}{n} \sum_{k=0}^{n-1} T(\max(k, n-k-1)) + \Theta(n)$$

$$\leq \frac{2}{n} \sum_{k=n/2}^{n-1} T(k) + \Theta(n)$$

- ▶ Let's show that $T(n) = O(n)$ by substitution

Analyzing Randomized Selection

- ▶ Assume $T(n) \leq cn$ for sufficiently large c :

$$\begin{aligned} T(n) &\leq \frac{2}{n} \sum_{k=n/2}^{n-1} T(k) + \Theta(n) \\ &\leq \frac{2}{n} \sum_{k=n/2}^{n-1} ck + \Theta(n) \\ &= \frac{2c}{n} \left(\sum_{k=1}^{n-1} k - \sum_{k=1}^{n/2-1} k \right) + \Theta(n) \\ &= \frac{2c}{n} \left(\frac{1}{2}(n-1)n - \frac{1}{2} \left(\frac{n}{2} - 1 \right) \frac{n}{2} \right) + \Theta(n) \\ &= c(n-1) - \frac{c}{2} \left(\frac{n}{2} - 1 \right) + \Theta(n) \end{aligned}$$

Analyzing Randomized Selection

- Assume $T(n) \leq cn$ for sufficiently large c :

$$T(n) \leq c(n-1) - \frac{c}{2} \left(\frac{n}{2} - 1 \right) + \Theta(n)$$

$$= cn - c - \frac{cn}{4} + \frac{c}{2} + \Theta(n)$$

$$= cn - \frac{cn}{4} - \frac{c}{2} + \Theta(n)$$

$$= cn - \left(\frac{cn}{4} + \frac{c}{2} - \Theta(n) \right)$$

$$\leq \underline{\underline{cn}} \quad (\text{if } c \text{ is big enough})$$

Average

Find a good pivot near the median first Worst-Case Linear-Time Selection

- ▶ Randomized algorithm works well in practice
- ▶ What follows is a worst-case linear time algorithm, really of theoretical interest only
- ▶ Basic idea: generate a good partitioning element
 - ▶ step1: divide n elements into $n/5$ groups
 - ▶ step2: find median of each group of 5 elements, using insertion-sorting
 - ▶ step3: recursively SELECT to find the median x of $n/5$ medians found in step 2. *Median of medians, close to the truth median.*
 - ▶ step 4: use x found in step 3 to partition the array, let k be one plus the number of elements in the low side of partition *more balance*
 - ▶ step 5: if $i=k$, return x ; else recursively SELECT i -th element in low side, if $i < k$; or SELECT $(i-k)$ -th element in high side, if $i > k$.

What's next...

- ▶ Hash Tables (Chapter 11)
- ▶ Binary Search Trees (Chapter 12)
